## 1.0 Introduction

A molluscan survey was undertaken in County Galway within the scheme study area for the N6 Galway City Transport Project. The survey concentrated on habitat areas with potential to support species that are protected by Annex II of the Habitat's Directive, particularly the *Vertigo* species.

The survey was carried from out from 11<sup>th</sup> August to 24<sup>th</sup> August 2014.

## 2.0 Scope of the study

The scope of the study was to carry out a comprehensive molluscan survey within the scheme study area for the N6 Galway City Transport Project, to inform the constraints study within the following remit:

 To assist in the provision of sufficient data from a molluscan perspective to identify the least damaging option, not only in terms of impacts on Special Areas of Conservation (SACs) / Special Protection Areas (SPAs) but also on nondesignated habitats for Annex II snail species;

- To determine if there are any currently undesignated populations of Annex II snail species which would qualify for SAC designation; and
- To determine if there are any undesignated areas of habitats of Annex II snail species which could qualify as 'damage' under the Environmental Liability Directive if impacted by the road.

# 3.0 Methodology

#### 3.1 Habitat identification

Molluscan surveys were undertaken in areas that were indicated by aerial photography and by wider habitat survey as having potential for Annex II molluscan species. Survey for the freshwater pearl mussel *Margaritifera margaritifera* is the subject of a separate report.

The habitats of the other 4 Annex II molluscan species are as follows:

Vertigo geyeri (from Moorkens & Killeen, 2011):

"The whorl snail *Vertigo geyeri* grows to less than 2mm in height. It is stringent in its requirement of saturated water conditions in calcareous, ground water fed flushes that are often limited in size to a few metres square. Their habitats often occur in mosaics of suitable patches within wider fen macrohabitats, that in Ireland can themselves fall within habitats that be as diverse as raised bog laggs, transition mires, lake shores, hill or mountain slopes, and wetlands associated with coastal dunes and machair (Moorkens, 2003). Within these macrohabitats, however, the snail is consistent in where it lives, within the saturated and decaying roots of small sedges (particularly *Carex viridula ssp. brachyrrhyncha*), associated fen mosses (particularly *Drepanocladus revolvens* and *Campyllium stellatum*).

Within its macrohabitat, the snail needs constancy of hydrological conditions, but with enough variation to provide refugia for the meteorological extremes that the habitat must endure. It requires an openness of habitat that prevents succession by shade loving plants and more competitive shade loving snails."

In the context of the habitat within the current constraints study, the potential habitat for *Vertigo geyeri* would be associated with spring fed slopes and seepage zones.

Vertigo angustior (from Moorkens & Killeen, 2011):

"The rare narrow-mouthed whorl snail *Vertigo angustior* grows to less than 2mm in height. At a broad level, it appears to be present in a very wide range of habitat categories of grassland, fen, marsh, salt marsh and flood plain, but the ecotone within which it is restricted means that the exact conditions which its presence demands are rare, and a lot of habitat that is "almost correct" is devoid of the snail, and other sites have an appropriate ecotone restricted to a narrow band only a few metres wide (but of

variable length). Sites where the species is widespread, especially those where a variety of suitable habitats and wetness conditions occur within the one general site are of high importance.

This snail is found associated with decaying vegetation in the litter layer, or in damp moss, in open unshaded habitats. Generally it occurs in open-structured, humid litter, but in very wet conditions can climb 10-15cm up the stems of plants or onto damp decaying timber. In dry conditions it may be found in the soil, just below the litter layer. In grassland situations it occurs at the base of tussocks and in fixed dune grassland among moss patches at the edge of dune slacks or higher and more widespread in dunes that have a naturally high water table or are subject to high levels of precipitation. It may also be found in and under flood debris.

This species requires friable and permanently moist litter, shaded by moderately tall herbaceous or grassy vegetation. It normally occurs in association with permanently moist but free-draining (permeable) soil, not subject to inundation. It is the latter requirement that makes seemingly suitable and widespread habitat unable to sustain a population of *V. angustior.*"

In the context of the habitat within the current constraints study, the potential habitat for *Vertigo angustior* would consist of a calcareous transition zone between wetland and free draining grassland, typified by *Iris* beds at the edge of wet fields, or silverweed (*Potentilla anserina*) patches in transition areas.

## Vertigo moulinsiana (from Moorkens & Killeen, 2011):

"The rare Desmoulin's whorl snail *Vertigo moulinsiana* is the largest of all the *Vertigo* species, growing to between 2.2 to 2.7mm in height. It lives on living and dead stems and leaves of tall plants in wetland situations.

As well as tall vegetation structure, *V. moulinsiana* requires a stable hydrogeology, where the water-table is at, or slightly above, the ground surface for much of the year and any seasonal flooding is of very low amplitude (Tattersfield & McInnes 2003). It climbs tall vegetation in the summer and autumn, and in winter it descends to litter level, and in severe conditions aestivates on the lower leaves of plants."

In the context of the habitat within the current constraints study, the potential habitat for *Vertigo moulinsiana* would consist of areas with a good distribution of tall *Carex* species, sometimes interspersed with *Schoenus nigricans* and *Phragmites australis*. It must be wet enough for water to rise and surround the surveyor's boot under light pressure. Extensive riverbank reedbeds with a sharp disconnection between the bank and the river makes *Vertigo moulinsiana* survival very unlikely, and similarly lake reedbeds with large water level changes are poor potential habitats, so areas with the most evenness of hydrology were surveyed.

#### Geomalacus maculosus (from Moorkens & Killeen, 2009):

"In Ireland, the Kerry slug is restricted to the sandstone geology of West Cork and Kerry. Within this range, it lives in two broad habitat types. The first type is oak dominated woodland, or mixed deciduous woodland with a mixture of oak and birch. The habitat is often sloping, with outcropping of rock or with boulders scattered amongst the trees. The second broad habitat is open situations of unimproved oligotrophic open moor or blanket bog with large sandstone boulders."

In the context of the habitat within the current constraints study, it should be taken into consideration that since the publication of this document in 2009, *Geomalacus* has been recorded in County Galway. However, within the scheme study area no potential habitat suitable for this species was identified. However, some potential for *Vertigo* habitat was identified.

Overall, initial surveys and aerial photography indicated that there were four main areas of potential *Vertigo* habitat:

- 1) Potential areas of reed swamp, wet grassland and fen along the Corrib River corridor;
- 2) Coolagh Lakes area;
- 3) Ballindooly Lough area;
- 4) Turlough features east of the Corrib.

#### 3.2 Methodology

At each site a wide area was investigated and the main habitats with the potential to support *Vertigo* species were sampled. Habitats were sampled by hand, e.g. examination of litter, stems and the underside of timber. Suitable habitat vegetation was sampled by banging leaves onto a white tray, and by the removal of amalgamated litter samples from areas of best potential for *Vertigo* species.

Approximately 2-3 litres of litter was taken from each sampling site, air dried in the laboratory and then sieved through two mesh sizes, 3mm and 0.5mm. The contents of each sieve were examined for snails. An Olympus 40X binocular microscope was used to examine the smaller species.

#### 4.0 Results

The habitat areas surveyed are shown in Figure 1, and described in Table 1. A total of 39 molluscan species were found in the survey, with a range of between 1 and 12 species per site. The full results of molluscan species found are shown in Table 2. Species are listed according to the nomenclature of Anderson (2005).

## 5.0 Discussion

There were no nationally or internationally rare or protected species found in this survey, but the species assemblage in some areas is of local interest.

There were no protected *Vertigo* species found in the field or in any of the samples, but three other *Vertigo* species *Vertigo* pygmaea, *V. antivertigo* and *V. substriata* were found at various sites, which suggests that the habitat conditions were not quite even in wetness and/or calcareous enough for the three Annex II *Vertigo* species. The rest of the species are typical of wet grassland, reedbed, riparian fringe and fen habitats. Together the sites display a good range of species assemblage with good variety across the sites, reflecting the level of variation in wetness and vegetative succession of different areas. It should be noted that *Vertigo antivertigo* is listed as vulnerable in the Irish Red Data List of molluscs (Byrne *et al.*, 2009).

The best areas of habitat for molluscs found were towards the southern end of Coolagh Lakes, concentrated in the area around Site 110, with high quality fen and transitional habitat. Here the most concentrated searches for *V. geyeri* were undertaken, but no individuals of this species were found in the field or in samples removed.

The scope of the study was to carry out a comprehensive molluscan survey within the study area for the N6 Galway City Transport Project, to inform the constraints study within the remit defined in Section 2. The study was based on ground truth surveys of areas chosen from aerial photographs and habitat studies. Unless further habitat survey identifies previously unknown areas of potential habitat, the sites surveyed are considered to be sufficient to draw conclusions. From the remit, the following conclusions can be drawn:

There is sufficient data from a molluscan perspective to conclude that there are no constraints from a molluscan perspective to the choice of option, not only in terms of impacts on SACs/SPAs but also on non-designated habitats for Annex II snail species, as no undesignated populations of Annex II snail species were found. Thus:

- There is sufficient data from a molluscan perspective to conclude that there will be no direct impacts on Annex II terrestrial snail species within the scheme study area;
- It is confirmed that there were no currently undesignated populations of Vertigo geyeri, V. angustior, V.moulinsiana or G. maculosus found which would qualify for SAC designation; and
- It is confirmed that there were no new populations of *Vertigo geyeri, V. angustior, V.moulinsiana* or *G. maculosus* found which could be impacted by the

construction or operation of the road and qualify as 'damage' under the Environmental Liability Directive.
